This checklist is automatically generated using Version 3.0 of the online database CDF Galapagos Species Checklist.

This checklist includes all lichen fungi that are currently known to occur in the Galapagos Islands. This list also includes some fungi typically associated with lichens (lichenicolous fungi, i.e., fungi parasitic or parasymbiotic on lichens) or often treated by lichenologists even though they are not lichenized. Lichens do not represent a taxonomic group, but are a classic example of a symbiosis, i.e., two very different organisms living together to form a new entity.

The outside shape and structure that we notice as a lichen is built by a fungus. Inside, this macroscopic structure hosts microscopic cells of green algae (Chlorophyta) or blue-green photosynthetic bacteria (Cyanobacteria).

The fungi that participate in this symbiosis belong to two taxonomic divisions (or phyla): Basidiomycota Ascomycota.

For marine species distribution data cited in the CDF Galapagos Checklists refer to the five main bioregions of the archipelago (Far Northern, Northern, Western, South Eastern and the Elithabeth Bay Bioregion). For the terrestrial species the more than 120 islands, islets and small rocks have been aggregated into Islands Groups, thus, for example, the island group "Santa Cruz" includes smaller islands like Santa Fé, Plaza Norte, Plaza Sur, Baltra, Daphne Mayor, Daphne Minor, and others.

Please be aware that the distribution data presented here is automatically generated from specimen records and does not always accurately reflect the known distribution for all species.

IUCN red-list assessments presented here may deviate from the global IUCN list for the following reasons:

- for well known species groups like vascular plants or vertebrates updates proposed to the IUCN are shown instead of the outdated, but currently accepted status;
- for poorly known species groups (e.g., lichenized fungi) a general assessment is currently not possible and the list presented here is a regional red-list list for Galapagos archipelago.

Names of taxa included in this checklist: 726 (522 Accepted , 5 Unidentified Taxon , 16 Doubtful , 53 Preliminary Identification , 15 Problematic , 9 New to Science), 106 rejected.

Origin of the taxa included: 1 Questionable Native, 35 Endemic, 502 Indigenous, 1 Questionable Endemic.

161. *Cyphellostereum sp.*
Taxon status: Unpublished name (Nomen nudum).
 F. Bungartz: Dictyonema phyllogenum f. defectum was described for a morphotype with a very poorly developed fungal sheath (Lücking 2008). Fig 258 E-F in Lücking (2008), however, depicts

cyanobacterial trichomes that are not closely bundled as it is the case in the Galapagos material. Also, trichomes of *Dictyonema phyllogenum* f. *defectum* are appressed rather than erect, as seen in the Galapagos material. The Galapagos specimens grow on a variety of substrates, one also found on leaves of the endemic *Miconia robertsoniana*, but most were collected on bryophytes. The micromorphology of these specimens is quite similar, but not identical with free-living forms of *Scytonema*, since *Cyphellostereum* sp. clearly presents fungal sheath cells surrounding the cyanobacteria.
